

## **Skin Lesion Types**

### **For use in ABCD Skin Lesion Detection Project**

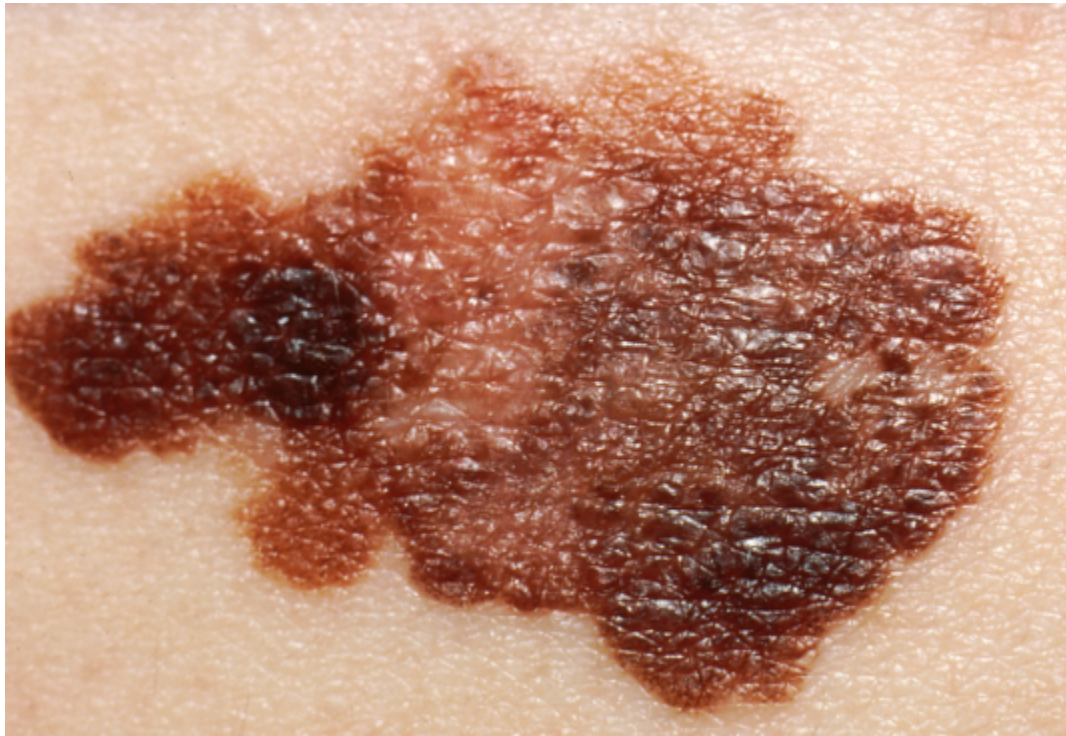

Melanocytic Nevus (nv):

These are common, benign growths made up of melanocytes (cells that produce pigment). They are commonly known as moles. Melanocytic nevi can be flat or raised and are typically brown or black in color. While most are harmless, they can occasionally transform into melanoma, especially if they change in size, shape, or color.

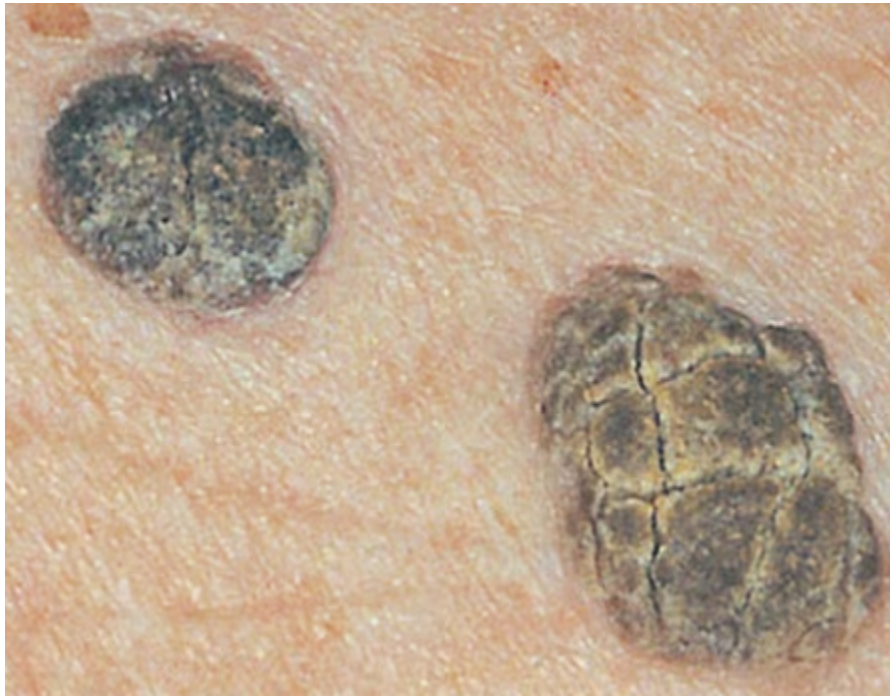

Melanoma (mel):

Melanoma is a type of skin cancer that originates in melanocytes. It is more aggressive and can spread to other parts of the body if not treated early. Melanoma usually appears as a new mole or changes in an existing mole, with irregular borders, multiple colors, and larger size. It's one of the most dangerous forms of skin cancer.

### Benign Keratosis-like Lesions (bkl):

These are non-cancerous growths that resemble keratosis, a thickening of the skin caused by the rapid growth of skin cells. They are often rough, scaly patches that appear as a result of sun exposure or aging. While they are benign, they can sometimes be mistaken for skin cancer.

### Basal Cell Carcinoma (bcc):

Basal cell carcinoma is the most common form of skin cancer. It originates in the basal cells (the lower part of the epidermis). BCC typically appears as a pearly or waxy bump, often with visible blood vessels. It grows slowly and rarely spreads to other parts of the body, but if left untreated, it can damage surrounding tissues.

### Actinic Keratoses (akiec):

Actinic keratoses are precancerous lesions caused by sun exposure. These are rough, dry, or scaly patches that can be red, brown, or flesh-colored. While they are not cancerous themselves, they have the potential to develop into squamous cell carcinoma, a type of skin cancer, if left untreated.

### Vascular Lesions (vasc):

Vascular lesions are abnormalities in the blood vessels of the skin. These can appear as red, purple, or blue marks and include conditions such as hemangiomas, port-wine stains, and spider veins. They can be congenital or acquired and vary in size and appearance. Most vascular lesions are benign, but they can sometimes signal other underlying health issues.

Dermatofibroma (df):

Dermatofibromas are benign, firm, raised growths that commonly appear on the arms or legs. They are made up of fibroblasts, a type of cell that produces collagen.

Dermatofibromas are typically brown or tan and may be mistaken for a mole. They are non-cancerous and often require no treatment unless they become painful or irritated
